## Rolling Bearings – Types and Features

### Design and Classification

Rolling bearings use balls or other rolling elements, located between bearing rings, to minimize friction. The rolling elements are separated and held in position by "cages" or other retaining devices.

The construction of six of the most common rolling element bearings are illustrated here for identification of nomenclature. Specific dimensions and details for these bearings are given in the dimensional tables in the preceding sections of this catalog.

In comparison to plain or sleeve type bearings, rolling bearings offer several advantages:

- Starting torque is minimal and the difference between starting torque and running torque is small.
- Rolling bearings can be designed to take both radial and axial loads simultaneously or independently.
- Rolling bearings can be preloaded to produce a negative clearance. This gives the bearing greater rigidity to constrain the radial and axial movement of a shaft relative to its housing.

Depending on the shape of their rolling elements, bearings fall into two main classes--ball bearings and roller bearings. Roller bearings are further classified by the specific shape of their rollers and by other individual features.

Bearings are also classified by function. For example, they can be classified as "radial," "thrust" or both, depending on the direction of the applied load and may be further classified as cylindrical, tapered, spherical or duplex depending on their configuration.

## Description and Features

Typical bearing configurations are described below:

**Deep Groove Ball Bearings** are the most common type of rolling element bearing. They have a single row of balls held in place by a cage, usually made of steel, that rotates between two rings with polished raceways. The design of the bearing allows for radial and axial loading while operating at high speeds. These bearings often come with shields or seals to protect the inside of the bearing from contamination in the application.

**Double Row Ball Bearings** have two rows of balls between two bearing rings. This is a back-to-back mounting of two single-row angular contact ball bearings, but their inner and outer rings are each integrated into one. This design allows for heavier axial loads in either direction and a significant radial load capacity. Some of these bearings are also available with shields and seals.

**Self-Aligning Ball Bearings** have an inner ring with two raceways. The outer ring has one spherical raceway and its center coincides with that of the bearing. Because of this, the axis of the inner ring, the balls and the cage can deflect around the bearing center. As a result, minor angular misalignment of the shaft, in relation to the bearing housing, can be accommodated. This type of bearing, with tapered bore, is often mounted using an adapter sleeve.

**Cylindrical Roller Bearings** have large radial load capacities. The rolling elements remain in linear contact with the bearing raceway and are precisely crowned to relieve the edge loading caused by shaft misalignment.

A cylindrical roller bearing in which either the inner or outer ring has no rib, may be used as free-end or floating bearing because its rings are free to move, in an axial direction, relative to each other. If either the inner or outer ring has two ribs and the other ring has one rib, the bearing is capable of taking a certain amount of axial load in one direction. Double row cylindrical roller bearings have high radial rigidity and are used primarily for precision machine tools.

**Tapered Roller Bearings** can take both radial and axial loads in one direction. They use conical rolling elements which are guided by ribs on the bearing's inner ring. The bearing rollers are precisely crowned near each end to relieve edge loading.

Since an axial force is generated in these bearings when a radial load is applied, they are often mounted in pairs, face to face, like single row angular contact ball bearings. When this is the case, the proper internal clearance can be obtained by adjusting the axial distance between the inner rings or outer rings of the two opposed bearings. Since they are separable, the inner and outer rings can be mounted independently.

Tapered roller bearings are divided into three types--normal, medium angle and steep angle--depending on the degree of contact angle. Double row tapered roller bearings are also available.

**Spherical Roller Bearings** are capable of handling both radial and axial loads in either direction and have excellent radial load carrying capacity. The line of contact between the barrel-shaped rollers and the outer ring raceway is a circular arc centered on the bearing axis. The outer ring raceway is spherical, making it self-aligning. There are two inner raceways and two rows of rollers.

Spherical roller bearings with tapered bores can be mounted directly on tapered shafts or on cylindrical shafts by using an adapter or withdrawal sleeve. Spherical roller bearings are available with pressed-steel, machined bronze or molded cages.

**Duplex Bearing Set** is a pair of radial bearings combined in various arrangements. It is often a combination of angular contact ball bearings or of tapered roller bearings. It may be a combination placed face to face (type DF) or back to back (type DB) or in tandem (type DT). Types DF and DB are capable of taking radial loads and axial loads in either direction. They may be modified to accommodate a variety of preloading requirements. Type DT is used when the application requires large axial loads in one direction.

**Single Direction and Double Direction Thrust Ball Bearings** are composed of washer-like bearing rings with raceway grooves for the balls. The ring attached to the shaft is called the inner ring or tight washer and the ring attached to the housing is called the outer ring or loose washer. In double direction thrust ball bearings there are three rings, with the center one fixed to the shaft.

Single direction thrust ball bearings can support axial loads in one direction; double direction, in two. There are also thrust ball bearings with an aligning seat washer beneath the outer ring to compensate for shaft misalignment or mounting errors.

**Spherical Roller Thrust Bearings** have a spherical raceway in the outer ring with the rollers obliquely arranged in a single row. Since the raceway in the outer ring is spherical, these bearings are self-aligning.

Spherical roller thrust bearings have a very high axial load capacity and are capable of taking moderate radial loads when an axial load is imposed. These bearings are suited for lower speeds and require oil for lubrication. They are assembled with pressed-steel cages or machined brass cages.

## Bearing Selection

The original equipment manufacturer (OEM) will select a bearing for their equipment based on the loading requirements of, and the space available for, the bearing. The bearing style and size provide the foundation for the bearing selection based on the load carrying capacity in relation to the loads to be carried.

### Selection Based on Basic Load Rating

The most common way to determine bearing life is by using the load ratings of the bearing and the loads required by the application. The common measurement is “**L<sub>10</sub>**” life, defined as the number of revolutions before metal fatigue first appears on 10% of a large group of like bearings. This is referred to as basic rating life or fatigue life. The equations for calculating **L<sub>10</sub>** life are:

$$\text{For ball bearings: } L_{10} = \left(\frac{C}{P}\right)^3 \quad \text{For roller bearings: } L_{10} = \left(\frac{C}{P}\right)^{10/3}$$

Where **L<sub>10</sub>**: Rating fatigue life (1 million Revs)

**P**: Bearing Equivalent Load (lbf, N, kgf), see below for calculation of **P**

**C**: Basic Load Rating (from catalog tables)

For radial bearings, **C=Cr** For thrust bearings, **C=Ca**

If the bearings run at a constant speed, it is convenient to determine **L<sub>10</sub>** life in terms of hours. This equation is expressed as

$$\text{For ball bearings: } L_{10h} = \frac{1,000,000}{60n} \left(\frac{C}{P}\right)^3 \quad \text{For roller bearings: } L_{10h} = \frac{1,000,000}{60n} \left(\frac{C}{P}\right)^{10/3}$$

Where **L<sub>10h</sub>**: Rating fatigue life in hours    **n**: Rotational speed, RPM

### Equivalent Bearing Loads (P)

To determine the value of **P**, you must first determine the effects of the radial and axial loads applied. Once this hypothetical load is determined, it is assumed to be constant in magnitude and direction. The general formula for the calculation of **P** is:  $P = X Fr + Y Fa$

Where **P**: Bearing equivalent load (lbf, N, kgf)

**X**: the Radial factor

**Fr**: the Actual constant radial load

**Y**: the Axial factor

**Fa**: the Actual constant axial load

The values for **X** and **Y** can be determined using the tables 10.2-10.4. First, determine the type of bearing being considered. Then, calculate the ratio of the axial load to the radial load and compare this to the bearings “**e**” value in the table.\* The “**e**” value is determined by multiplying the axial load applied to the bearing by the bearing coefficient factor, **f<sub>0</sub>**, which is obtained from the bearing tables. Divide the result by the static radial load rating. Locate the result in the first column and read across to find the “**e**” value. (In the case of angular contact bearings, the “**i**” value must be used. If a duplex pair in a DB or DF configuration is used, the “**i**” value is 2.) In effect, if the axial load is small compared to the radial load, then only the radial load is considered. If not, then a combination of the two is used. After determining the equivalent bearing load, **P**, the **L<sub>10</sub>** formula given above can be used to determine the **L<sub>10</sub>** life with 90% reliability for a given bearing’s basic load rating. Also, for a required **L<sub>10</sub>** life, a basic load rating requirement can be found for bearing selection.

### Correction of Basic Load Rating Due to Temperature

The operating temperature will significantly affect the fatigue life by altering the hardness of the bearing. Consequently, the basic load rating, which depends on the physical properties of the bearing material, will decrease with higher temperatures. Thus, the basic load rating must be corrected for higher temperatures using the equation:  $C_t = f_t \cdot C$

Where  $C_t$ : Basic load rating after temperature correction

$f_t$ : Temperature factor (see following table)

$C$ : Basic load rating from tables, before application of temperature correction.

**Table 10.5 — Temperature Factor ( $f_t$ )**

	Bearing Temperature (°C)			
	≤150	175°	200°	250°
Temperature Factor $f_t$	1.00	.95	.90	.75

### Adjustments to Fatigue Life Rating

Each style of bearing has many characteristics that make that bearing better suited for an application than another bearing. For example, some common applications require a bearing that can handle misalignment, loads in both directions, high speeds, etc..., or a combination of two or more. These operating conditions will alter the bearing life and are accounted for by using correction factors for temperature, reliability, bearing material, and other operating conditions. For the complete list of adjustment factors and their values, please contact NSK engineering or refer to NSK catalog E1101a.

The formula for adjusting life based on reliability, material, and operating conditions is:

$$L_{na} = a_1 * a_2 * a_3 * L_{10}$$

Where  $L_{na}$ : Adjusted life rating.

$L_{10}$ : Life rating, adjusted for fatigue life for 90% reliability. This may not satisfy all applications. For higher reliability requirements,  $L_{10}$  must be adjusted.

$a_1$ : Life correction factor for reliability. This is determined from the reliability required of the bearing for its application (see table below).

$a_2$ : Life correction factor for bearing material.

$a_3$ : Life correction factor for operating conditions

Values of  $a_2$  and  $a_3$  are difficult to determine, however, for most applications,  $a_2 * a_3 = 1$  can be assumed. If you have concerns about lubrication viscosity, temperature, contamination, misalignment, or other operating abnormalities, please consult NSK Engineering.

**Table 10.6 — Reliability Factor ( $a_1$ ).**

	Reliability					
	90%	95%	96%	97%	98%	99%
$a_1$	1.00	.62	.53	.44	.33	.21

### Static Load Rating

Some applications are stationary with loads for long periods, rotate at very low speeds, are subjected to slow oscillations, or are exposed to shock loads. In these events, the static load rating ( $C_{0r}$  or  $C_{0a}$ ) must be used in the life calculations. Please contact NSK engineering for more details.

### Selection Based on Dimensions

For single row bearings having the same width series, diameter series, and bore size, all styles have the same bore, O.D., and width. For example, 6203, NJ203, and 7203 all have a 17mm bore, a 42mm O.D., and 12mm width. Therefore, selection can be made based on the requirements of the application such as, speeds, misalignment capabilities, bearing value, etc..., provided that the life requirement is met by the bearing style.

## Bearing Identification

### Bearing Number Formulation

Bearings are identified by numbers and letters which designate bearing type, boundary dimensions, tolerance class, internal clearance and other specifications. The numbers used for standard bearings conform to ISO 15, Designation of Rolling Bearings.

Boundary dimensions for the most commonly used bearings are based on the ISO Boundary Dimensions Tables.

In order to establish certain standards in addition to those specified in ISO, NSK also uses various symbols of its own.

## Bearing Tolerances

### BEARING TOLERANCE STANDARDS

The dimensional and running accuracies of rolling bearings are standardized by ISO with regard to the following items:

- Tolerances for bore diameter, outer diameter, individual ring width, and overall width.
- Tolerances for absolute dimensions of inscribed circle diameter and circumscribed circle diameter.
- Tolerances for chamfer dimension.
- Tolerances for width variations
- Tolerances for taper angle and taper bore diameters
- Tolerances for radial runout of inner ring and outer rings.
- Tolerances for axial runout of inner and outer rings.
- Tolerances for side or face runout of inner ring.
- Tolerances for side or face runout of outer ring.

In grading bearing tolerances, ISO “normal class” represents the standard. ISO classes 6, 5, 4, and 2 represent four higher grades. In general, DIN, JIS, and ABMA tolerance classes conform to these ISO standards. Tolerance classes applicable to each bearing type are shown in the subsequent tables.

## Bearing Tolerance Nomenclature

Rough definitions of the items listed above for running accuracy and their measuring methods are shown below. They are described in detail in ISO 5593 (Rolling Bearings-Vocabulary), JIS B 1515 (Measuring Methods for Rolling Bearings), and elsewhere.

**Symbols for Boundary Dimensions and Running Accuracy**

$d$ Bearing bore diameter, nominal	$\Delta_{Ts}$ Deviation of the actual bearing width
$\Delta_{ds}$ Deviation of single bore diameter	$D$ Bearing outside diameter, nominal
$\Delta_{dmp}$ Single plane mean bore diameter deviation	$\Delta_{Ds}$ Deviation of a single outside diameter
$V_{dp}$ Bore diameter variation in a single radial plane	$\Delta_{Dmp}$ Single plane mean outside diameter deviation
$V_{dmp}$ Mean bore diameter variation	$V_{Dp}$ Outside diameter variation in a single radial plane
$B$ Inner ring width, nominal	$V_{Dmp}$ Mean outside diameter variation
$\Delta_{Bs}$ Deviation of a single inner ring width	$C$ Outer ring width, nominal
$V_{Bs}$ Inner ring width variation	$\Delta_{Cs}$ Deviation of a single outer ring width
$K_{ia}$ Radial runout of assembled bearing inner ring	$V_{Cs}$ Outer ring width variation
$S_d$ Inner ring reference face (backface, where applicable) runout with bore	$K_{ea}$ Radial runout of assembled bearing outer ring
$S_{ia}$ Assembled bearing inner ring face (backface) runout with raceway	$S_D$ Variation of bearing outside surface generatrix inclination with outer ring reference face (backface)
$S_i, S_e$ Raceway to backface thickness variation of thrust bearing	$S_{ea}$ Assembled bearing outer ring (backface) runout with raceway
$T$ Bearing width, nominal	

**Measuring Methods for Running Accuracy (summarized)**

Illustrations	Running Accuracy	Inner Ring	Outer Ring	Dial Gage

Note: 1) 2.5 mm is included within this group.  
Remarks: 1) The outside diameter low tolerances specified in this table do not apply within a distance of 1.2 times the chamfer dimension *r* (max) from the ring face.  
2) The cylindrical bore diameter "no-go" side" tolerance limit (high) specified in this table does not necessarily apply within a distance of 1.2 times the chamfer dimension *r* (max) from the ring face.  
3) ABMA Std 20-1987 was amended: ABEC1 ° RBEC1, ABEC3 ° RBEC3, ABEC5 ° RBEC5, ABEC7, and ABEC9 are equivalent to Classes N, 6,5,4, and 2 respectively.

Remarks: 1. The outside diameter "no-go side" tolerances (high) specified in this table do not necessarily apply within a distance of 1.2 times the chamfer dimension *r* (max) from the ring face.  
 2. Some of these tolerances conform to the NSK standard, and not ISO standards.

## Bearing Fits & Internal Clearance

### Fit--Why It's Important

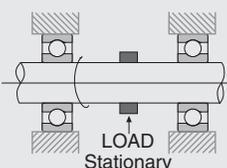

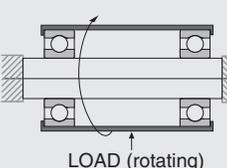

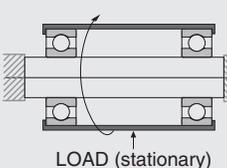

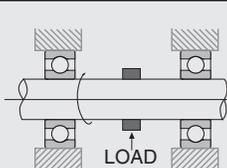

When a bearing's inner ring is fitted to the shaft with only slight interference, slipping or "creep" may occur. Creep may also occur between the outer ring and housing.

When creep occurs the fitted surfaces become abraded which causes excessive wear and may cause considerable damage to the shaft or housing. In addition, abrasive metal particles resulting from creep may enter the interior of the bearing and cause abnormal heating and vibration.

It is important to prevent creep by having sufficient interference to firmly secure the bearing ring to either the shaft or housing.

In specific applications, fits can be made without interference. For example, it is usually not necessary to provide fit interference for rings subjected only to stationary loads. In other applications, loose fits may be used to accommodate certain operating conditions or to facilitate bearing mounting and dismounting. In these cases, lubrication or other methods need to be considered to prevent damage to the fitting surfaces due to creep.

## Bearing Internal Clearance

### Internal Clearances and Standards

Bearing internal clearance is the total clearance between the rings and rolling elements. Internal clearance influences fatigue life, vibration, noise, and operating temperature. Therefore, selection of the proper clearance is critical.

Radial and axial clearances are defined as the total amount that one ring can be displaced relative to the other in either the radial or axial direction as shown in this drawing.

To obtain accurate measurements for ball bearings, internal clearance is usually measured by applying a specified measuring load to the bearings. The clearance measured is always slightly larger than the actual bearing internal clearance due to the elastic deformation caused by the measuring load.

Actual internal clearance is obtained by correcting the measured clearance by the amount of elastic deformation. In the case of roller bearings this elastic deformation is negligible.

Bearing internal clearances listed throughout this catalog have been corrected to provide actual internal clearances.

### Radial Internal Clearance

Radial Internal Clearances for several types of ball bearings and roller bearings are presented in the following tables:

### SELECTION OF BEARING INTERNAL CLEARANCE

By way of definition, "Normal Operating Conditions" for bearings occur when the bearing load does not exceed the equivalent load ( $P=0.1C$ ), the inner ring is tight-fitted to the shaft and operating speed is less than 50% of the limiting speed given in the bearing tables. For the replacement market the standard clearance group, **C3**, is used for "Normal Operating Conditions." However, there are six standard clearance groups, designated as **C1**, **C2**, **C0**, **C3**, **C4** and **C5**. **C1** represents minimum clearance and **C5** represents maximum clearance.

Selection of the proper bearing clearance varies with required fits, loads, speeds, and operating temperatures. Each of these will reduce the initial internal clearance a certain amount. Changes that occur in the radial clearance of roller bearings are shown in Figure 10.42.

**FIGURE 10.42 — CHANGES OF RADIAL INTERNAL CLEARANCE OF BEARING**

## CHANGES IN RADIAL INTERNAL CLEARANCE

### Decrease in Radial Clearance Due to Fit

When the inner or outer ring is tight-fitted to the shaft or the housing, a decrease of radial internal clearance is caused by the expansion or contraction of the bearing rings. The decrease varies according to the bearing type, bearing size and shape, and design of the shaft or housing. The amount of decrease normally ranges from 70 to 90% of the interference.

The internal clearance after mounting is obtained by subtracting the interference decrease,  $\Delta f$ , from the initial internal clearance.

### Temperature Effects on Radial Internal Clearance

Under normal operation, the radial internal clearance of a bearing will decrease because of the temperature differences between the inner and outer rings. Typically, the temperatures of the inner ring and the rolling elements are higher than that of the outer ring by 8 to 15°F. When the shaft is heated or when the housing is cooled, the difference between the inner and outer rings is even larger.

The amount of decrease due to thermal expansion can be calculated from the following equations:

$$\delta_t = \alpha \Delta_t D_e$$

Where  $\delta_t$ : Internal clearance decrease (inch) due to temperature

$\alpha$ : Coefficient of linear expansion of bearing steel ( $12.5 \times 10^{-6}$ ) ( $1/^\circ\text{C}$ )

$\Delta_t$ : Temperature difference between inner & outer rings ( $^\circ\text{C}$ )

$D_e$ : Outer ring raceway diameter (inch)

**For Ball Bearings:**  $D_e = \frac{1}{5}(4D + d)$

**For Roller Bearings:**  $D_e = \frac{1}{4}(3D + d)$

Where **D**: Bearing outside diameter (inch)

**d**: Bearing bore diameter (inch)

### Effective Clearance

The effective, or operating, clearance  $\Delta$  is obtained by subtracting  $\delta_t$  from the internal clearance after mounting  $\Delta_f$ . Theoretically, the longest life of a bearing can be expected when the effective clearance is slightly negative. However, it is difficult to achieve this condition and excessive negative clearance will shorten bearing life. Therefore, a clearance of zero or a slightly positive value is preferable.

Angular contact ball bearings or tapered roller bearings normally require the user to set the internal clearance at mounting. The user should check the proper orientation of these bearings by checking the original bearings or the service manual for the machine. A check should also be made for the recommended set clearance. This can be obtained from the service manual, the machine manufacturer, or the bearing manufacturer.

## Preloaded Bearings

### Types and Features

Rolling bearings usually retain some internal clearance while in operation. However, in some cases it is desirable to provide a negative clearance. This is called "preloading." Preloading can be used to decrease bearing deflection and provide greater bearing rigidity. However, it may also increase power consumption and reduce bearing life.

A preload is usually given to those types of bearings in which the axial clearance can be adjusted in mounting--for example, angular contact ball bearings and tapered roller bearings. Usually preloaded bearings are mounted face to face or back to back to form a duplex bearing set.

### WHY PRELOAD?

Typical reasons and applications for preloading bearings are:

- To maintain bearings in an exact position in both the radial and axial directions and to maintain the running accuracy of the shaft... for example, the main shaft of machine tools and instruments.
- To increase bearing rigidity. This is often needed on the main shaft of machine tools or the pinion shaft of automobile differentials.
- To minimize noise due to axial vibration and resonance... for example, in high speed or high acceleration applications of angular contact ball bearings and thrust ball bearings
- To prevent sliding due to the gyratory movement of rolling elements... for example, in high speed or high acceleration applications of angular contact ball bearings and thrust ball bearings.
- To maintain the rolling elements in their proper position with the bearing rings... for example, on thrust ball bearings and spherical roller thrust bearings mounted on a horizontal shaft.

### HOW TO PRELOAD DUPLEX BEARINGS

There are two basic methods for preloading duplex bearings--preloading by position and preloading by constant pressure:

#### Position Preload

Position preload is achieved by positioning two axially opposed bearings while maintaining their relative positions in operation. This is usually done by one of the following methods:

- Installing a duplex bearing set with previously adjusted stand-out dimensions and axial clearance.
- Using a spacer or shim with proper dimensions to obtain the required spacing and preload. See Figure 10.43.
- Using bolts or nuts to allow adjustment of the axial clearance. In this case the starting friction torque should be measured to verify the proper preload.

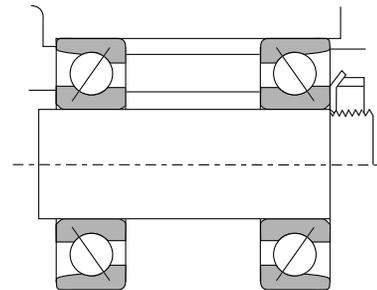

Figure 10.43 — Example of Position Preload

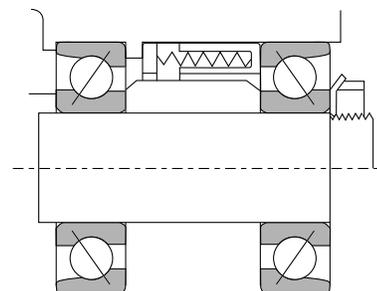

Figure 10.44 — Example of Constant Pressure Preload

## Constant Pressure Preload

Constant pressure preload is achieved by using a coil or leaf spring to impose a constant preload. Even if the relative position of the bearings changes during operation, the magnitude of the preload remains relatively constant. See Figure 10.44

## SELECTING PRELOADING METHOD AND THE AMOUNT OF PRELOAD TO USE

### Comparison of Preloading Methods

A comparison of rigidity using different preloading methods is shown in the chart below.

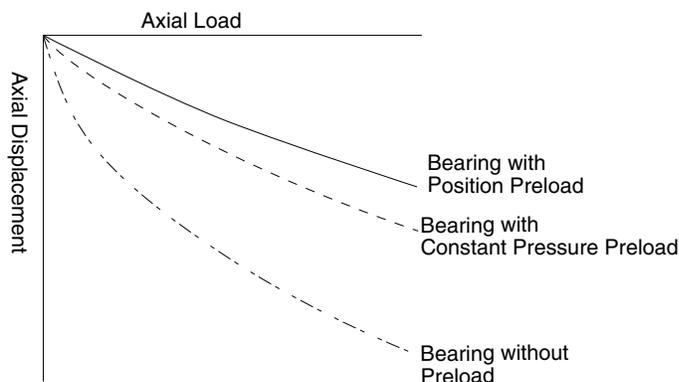

Figure 10.45 — Preload and Rigidity

Position preloading is generally preferred for increasing rigidity. Constant pressure preload is more suitable for high speed applications, prevention of axial vibration, and for use with thrust bearings on horizontal shafts. Position preload and constant pressure preload each offer specific advantages:

- When equal preloads are imposed, the position preload provides greater bearing rigidity. The deflection due to external loads is less for bearings with a position preload.
- In position preloading the level of preload varies depending on such factors as a difference in axial expansion due to a temperature difference between the inner and outer rings and deflection due to load.
- In constant pressure preloading it is possible to minimize any change in the preload because the variation of the spring load with shaft expansion and contraction is negligible.

### How Much Preload to Use?

If the preload is larger than necessary, abnormal heat generation, increased frictional torque and reduced fatigue life may occur. The amount of the preload should be determined considering the operating conditions, the purpose of the preload, and the type of bearing to be preloaded.

**Preload of Duplex Angular Contact Ball Bearings** — The average preloads for duplex angular contact ball bearings (contact angle of 15°) with precision better than P5 class are listed in the tables on the following page. These bearings are used on the main shafts of machine tools.

The recommended fits between the shaft and inner ring, and between the housing and outer ring are listed in Table 10.31 on page 328 thru Table 10.34 on page 329.

For housing fits, the lower limit of the fit range should be selected for fixed-end bearings and the upper limit for free-end bearings.

As a general rule, an extra light or light preload should be selected for spindles of grinders and a medium preload should be selected for the main shafts of high speed lathes and milling machines.

### Preload of Thrust Ball Bearings

When the balls in thrust ball bearings rotate at relatively high speeds, sliding due to the gyratory movement of the balls may occur. The larger of the two values obtained from the equations below should be selected as the minimum axial load in order to prevent such sliding.

$$F_{a,min} = \frac{C_{oa}}{100} \left( \frac{n}{N_{max}} \right)^2$$

Where  $F_{a,min}$ : Minimum axial load, N  
 $C_{oa}$ : Basic static load rating, N  
 $n$ : Rotational speed, rpm  
 $N_{max}$ : Limiting speed (oil lubrication), rpm

### Preload of Spherical Roller Thrust Bearings

When spherical roller thrust bearings are used a preload is necessary to keep the rollers in proper position against the outer ring raceway. The minimum axial load  $F_{a,min}$  necessary to do this is:

$$F_{a,min} = \left( \frac{C_{oa}}{1000} \right)$$

## Bearing Lubrication

### LUBRICATION--THE PURPOSE

Lubrication is needed to reduce friction and wear inside the bearing. Proper lubrication and procedures will allow the bearing to reach its expected life.

Primarily, lubrication serves the following purposes:

- Reduces Friction and Wear – Direct metallic contact between the bearing rings, rolling elements and cage is prevented by an oil film which reduces the friction and heat at the contact areas.
- Extends Bearing Life – The rolling fatigue life of bearings depends in a large part on the viscosity and film thickness of the lubricant. A heavy film thickness prolongs the bearing fatigue life.
- Cooling – Circulating oil can be used to carry heat away from the bearing. A circulating system is normally used when excessive heat is generated by the bearing due to high speeds, high loads, or when heat from a source adjacent to the bearing can affect its operation. Oils deteriorate at high temperatures; therefore it is important to keep both the oil and the bearing cool.
- Other Purposes – Proper lubrication also helps to prevent foreign material from entering the bearings, and protects against corrosion or rusting.

### SELECTING THE CORRECT LUBRICATION METHOD

Lubrication can be accomplished by using either oil or grease. The most satisfactory bearing performance will be achieved by selecting the method most suitable for a specific application. This of course will also depend on the conditions under which the bearing will operate.

Oil lubrication is superior in lubricating efficiency, however, grease lubrication allows a simpler structure around the bearings. The following table compares oil and grease lubrication.

Operating Factor	Grease Lubrication	Oil Lubrication
Housing Structure and Sealing Method	Simple	May be complex. Careful maintenance required.
Speed	Limiting speed is 65% to 80% of that of oil lubrication	High limiting speed
Cooling Effect	Poor	Heat transfer is possible using forced oil circulating lubrication
Fluidity	Poor	Good
Full Lubricant Replacement	Sometimes difficult	Easy
Removal of Foreign Matter	Removal of particles from grease is impossible	Easy
External Contamination Due to Leakage	Surroundings seldom contaminated by leakage	Often leaks without proper countermeasures. Not suitable if external contamination must be avoided

### GREASE LUBRICATION

#### Grease Quantity

The quantity of grease to be packed in a housing depends on the housing design, rotational speeds of the bearings, characteristics of the grease selected, and the ambient temperature conditions. These factors are critical to satisfactory performance.

In applications where the operating speed does not exceed one-half the rated limiting speed of the bearing, the bearing should be packed one-half to two-thirds full. If the speed of the bearing exceeds one-half the limiting speed, the quantity of grease should be reduced to one-third to one-half full and periodic regreasing scheduled. When operating conditions are not severe, the original pack of grease should last a long time without replenishment. If the operating conditions become severe, it will be necessary to regrease periodically.

Care should be taken to avoid excessive greasing as this will cause bearings to overheat.

## GREASE REPLENISHMENT

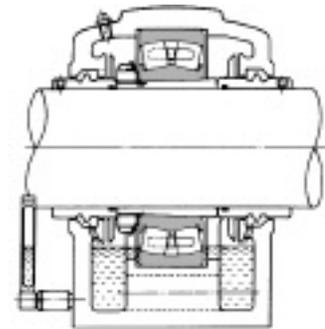

Frequent grease replenishment is required when operating conditions are severe such as in high ambient temperatures or where contaminants can enter bearing housings. Routine regreasing schedules should be established. In cases where extremely severe conditions exist or the bearings are in a remote area, the bearing housing should be designed to make replenishment and replacement as simple as possible. Automatic grease systems are available and should be used.

For normal operating conditions, it may be necessary to regrease the bearing periodically to replace any grease which has leaked from the housing and to eliminate any deteriorated grease.

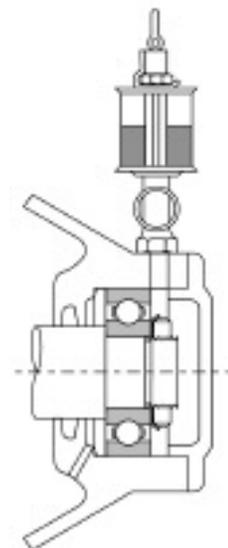

## OIL LUBRICATION

When the operating speed exceeds the grease limiting speed listed for the bearing, oil lubrication should be used. Several methods are available and are described below. The best method to use will depend on operating conditions.

**OIL BATH LUBRICATION** is a common method used where bearings are operating below the listed oil limiting speed. The static oil level should be set at the center of the lowest rolling element. An oil sight level gauge should be included in the system so that proper oil level can be quickly monitored.

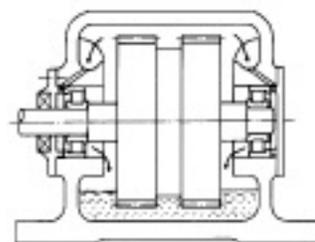

**DRIP FEED LUBRICATION** is often used for small bearings operated at relatively high speeds. In the illustration, a visible oiler is used. The oil drip rate is controlled by a screw valve located at the top of the oil cup.

Introduction

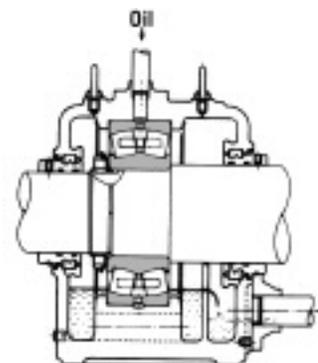

**Splash Lubrication** – In this lubricating method, oil is splashed onto the bearings by gears or by a simple rotating disc. This method is commonly used in automobile transmissions, differentials and gear boxes. The illustration shows splash lubrication used on a reduction gear.

Ball Bearings

Cylindrical Roller Bearings

**Circulating system** lubrication is commonly used for high speed operation and for bearings used at high temperatures. As shown in the illustration, oil from the supply pipe circulates through the bearings and exits to an external reservoir. After cooling in the reservoir it returns to the bearing through a pump and filter. In a circulating system, the oil outlet should be larger in diameter than the supply pipe so that an excessive amount of oil will not remain in the housing.

**Oil Mist Lubrication**, – also called oil fog lubrication, uses air to atomize the oil and carry it into the bearing. This method is used in bearings for the ultra high-speed spindles of machine tools, high-speed rotary pumps, and roll necks of rolling mills, as shown in the illustration.

In **Oil/Air Lubrication** systems, a small quantity of oil is periodically injected into an air stream which carries it to the bearing. This system is used when it is necessary to precisely control the quantity of oil entering the bearing to control operating temperature.

## Lubricants

### LUBRICATING GREASE

Grease is a semi-solid lubricant of a base oil and a thickener. Other ingredients are sometimes added to impart special properties to the base.

The main types and general properties of grease are shown in Table 10.50 on page 343. It should be noted that different brands of the same type of grease may have different properties.

**Base Oil** – Mineral oil or synthetic oils such as silicon or diester oil, are commonly used as the base oil for grease. The lubricating properties of grease are dependent on the characteristics of its base oil. The viscosity of the base oil is an important consideration when selecting grease. Usually grease made with a low viscosity base oil is more suitable for high speeds and low temperatures while grease made with high viscosity base oils is more suited for high temperatures and heavy loads. The thickener also influences the lubricating properties of grease, therefore selection criteria for grease are not the same as for lubricating oil.

**Thickener** – Several types of metallic soaps, inorganic compounds such as silica gel and bentonite, and heat resisting organic thickeners such as polyurea and flouric compounds are used as thickeners for grease. The water resistance properties of grease depend on the type of thickener. Sodium soap grease (or compound grease containing sodium soap) emulsifies when exposed to water or high humidity and therefore cannot be used where moisture is prevalent. Lithium soap grease, on the other hand, is recommended where moisture is present because of its resistance to wash off.

For applications where the operating temperature exceeds the limitation of common multi-purpose grease, greases having complex bases or non-soap bases are recommended. The grease used should also have a synthetic oil to withstand rapid deterioration at high temperatures. If the grease used in a high temperature application uses a mineral oil, it should be replenished frequently as deterioration of the oil will be accelerated at high temperatures.

**Additives** – Grease often contains a variety of additives such as antioxidants, corrosion inhibitors, and extreme pressure additives to give it special properties. Extreme pressure additives are recommended for use in heavy load applications. For long use without replenishment, an antioxidant should be added.

**Consistency** – Consistency indicates the “softness” of the grease. The following table shows the relationship between consistency and working conditions.

		<b>Consistency Number</b> (Given by the National Lubricating Grease Institute (NLGI) Scale)				
		<b>0</b>	<b>1</b>	<b>2</b>	<b>3</b>	<b>4</b>
Consistency <sup>1)</sup> (1/10 mm)		385~355	340~310	295~265	250~220	205~175
Working Condition		For centralized oiling. When false brinelling is liable to occur.	For centralized oiling. When fretting is liable to occur. For low temperature.	For general use. For sealed bearings.	For high temperature. For general use. For sealed bearings	For high temperature. For grease seals

1) Consistency: Depth into grease attained by a cone when pressed with a specified weight, indicated in units of 1/10 mm. The larger the value, the softer the grease.

**Mixing Different Types of Grease** – In general, grease of different types must not be mixed. Mixing grease with different types of thickeners may destroy the composition and physical properties of the grease. Even if the thickeners are of the same type, possible differences in the additives may cause detrimental effects.

Remarks	General purpose lubricant.	Good low temperature and torque characteristics. Often used for small motor and instrument bearings	Mainly for high temperature applications. Unsuitable for bearings under high speed or heavy load conditions or for sliding contact areas (roller bearings)	Long and short fiber types available. Long fiber grease is not suitable for high speeds or for sliding contact areas (roller bearings)	Not suitable for high temp. and heavy loads. Extreme pressure grease containing high viscosity oil and extreme pressure additive (Pb soap, etc.) is available	Often used for roller bearings and large ball bearings	Suitable for extreme pressures. Mechanically stable.	Medium and high temperature lubricant	Recommended for special environments with very high and low temperatures, acids, alkalis, radioactivity, and exposure to flames.

## Lubricating Oil

Lubricating oil used for bearings is usually a highly refined mineral or synthetic oil which has a high film strength and superior oxidation and corrosion resistance. When selecting an oil, the viscosity of the operating conditions is very important. If the viscosity is too low, a proper oil film is not formed and abnormal wear and seizure may occur. On the other hand, if the viscosity is too high, excessive viscous resistance may cause heating or a large power loss. In general, low viscosity oils should be used at high speeds. Higher viscosity oils should be used for heavy loads or for the larger bearings. The following table shows the generally recommended viscosity for certain bearing types.

Bearing Types	Proper Viscosity at the Operating Temperature
Ball Bearings and Cylindrical Roller Bearings	Higher than 13 cSt
Tapered Roller Bearings and Spherical Roller Bearings	Higher than 20 cSt
Spherical Roller Thrust Bearings	Higher than 32 cSt

The following chart shows the relationship between temperature and viscosity for use in selection of the proper lubricating oil.

**Table 10.51 – Temperature – Viscosity Chart**

**Oil Replacement Interval** – The oil replacement interval depends on the operating conditions and oil quantity. In those cases where the operating temperature is less than 120°F and the environmental conditions are good, oil should be replaced approximately once a year. However, where the oil temperature is about 212°F the oil must be changed at least once every three months.

In dirty environmental conditions, or if moisture or foreign material is mixed in the oil, the replacement interval must be shortened.

Mixing different brands of lubricating oil should be avoided.

## HOW TO HANDLE BEARINGS

Rolling bearings are high precision machine parts and need to be handled carefully. When installing or removing a bearing, correct procedures should be followed. Careless handling during mounting and removal could result in a serious accident, injuring people and damaging property.

Whether installing, removing, mounting, dismounting, replacing or inspecting, a few simple precautions must be followed:

### Keep Bearings and Surroundings Clean!

Dust and dirt, even if invisible to the naked eye, can harm bearings. To prevent the entry of dust and dirt, keep bearings and their environment as clean as possible. Never remove a bearing from its package until you are ready to mount it.

### Handle With Care!

Heavy shocks during handling may cause bearings to be scratched or otherwise damaged. Excessively strong impacts when mounting, dismounting or handling may cause brinelling, breaking or cracking.

### Use Proper Tools!

Always use the proper equipment and tools to install or remove bearings. Avoid using general purpose tools such as hammers, screwdrivers, wrenches and pliers.

### Protect Bearings From Corrosion!

Keep hands clean when handling bearings. Perspiration and other contaminants on the hands can cause corrosion on the bearings. Wear gloves, if possible. Apply oil or grease to non-sealed bearings immediately after installation for further protection.

## MOUNTING--FACTORS TO CONSIDER

Bearings are very precise and their mounting requires careful attention. The following items must be considered:

- Cleaning related parts
- Dimensions and finish of related parts
- Mounting procedures
- Inspection after mounting
- Supply of lubricants.

Prelubricated bearings and bearings lubricated with ordinary oil or grease should not be washed before installation. The preservative used on the bearing to protect it during storage is compatible with most common lubricants.

Bearings used for instruments or high speed applications, such as machine tool bearings, can be washed before installation to remove the anti-corrosion agent used in manufacturing. These bearings must be washed in clean, filtered oil and protected from corrosion until they are installed and lubricated.

Bearing mounting methods depend on bearing type and the type of fit. As bearings are usually used with rotating shafts, the inner rings require a tight fit. Bearings with cylindrical bores are usually

mounted by pressing through the inner ring on the shafts (press fit) or heating them to expand their diameter (shrink fit). Bearings with tapered bores can be mounted directly on tapered shafts or on cylindrical shafts by using tapered sleeves.

Bearings are usually mounted in housings with a loose fit. However, if the outer ring has an interference fit, a press may be used. Bearings can be interference fitted by cooling before mounting, using dry ice. If this is done, a rust preventive treatment must be applied to the bearings because moisture in the air will condense on bearing surfaces.

## MOUNTING BEARINGS WITH CYLINDRICAL BORES

**Press Fits** – Fitting with a press is widely used for small bearings. Before mounting, oil should be applied to the fitted shaft surface to make insertion smoother. A mounting tool is placed on the inner ring as shown in Figure 10.52. The mounting tool must not be placed on the outer ring for press mounting, because this may damage the bearing. The bearing is slowly pressed onto the shaft until the side of the inner ring rests against the shoulder of the shaft.

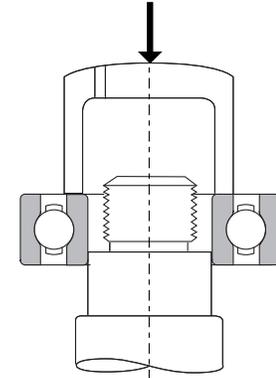

Figure 10.52 – Press Mounting of Inner Ring

Using a hammer for mounting should only be done if pressing equipment is not available. Any time a hammer is used, a mounting tool must be placed on the inner ring. For tight interference fits or for medium and large bearings, a hammer should never be used.

When both the inner and outer rings of non-separable bearings, such as deep groove ball bearings, require a tight fit, a mounting tool should be placed on both rings and both rings fitted at the same time using a screw or hydraulic press. See Figure 10.53.

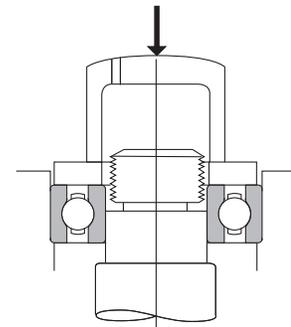

Figure 10.53 – Simultaneous Press Mounting of Inner & Outer Ring

When mounting separable bearings, such as cylindrical roller bearings and tapered roller bearings, the inner and outer rings may be mounted separately.

A mounting tool such as that shown in Figure 10.53 should also be used for mounting self-aligning bearings. Assembly of the inner and outer rings which were previously mounted separately must be done carefully to align them correctly. Careless or forced assembly may cause scratches on the rolling contact surfaces.

**Shrink Fits** – Shrink fitting is often used to avoid the large force involved in press fitting large bearings. This method eliminates the need to impose excessive force on the bearings. For shrink fitting, the bearings are first heated in oil, or in an induction heater, to expand them, then mounted and allowed to cool.

This amount of expansion of the inner ring for various temperature differences and bearing sizes are shown in Figure 10.54

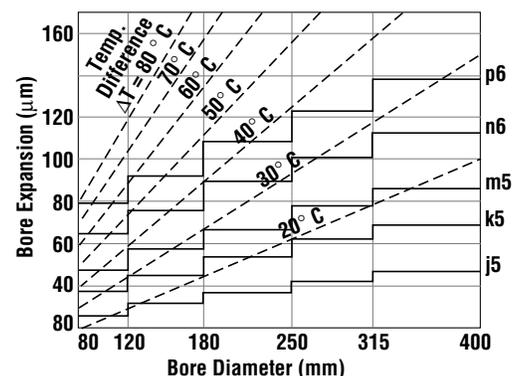

Figure 10.54 – Temperature and Expansion of Inner Ring

A few precautions to be considered when making shrink fits:

- Do not heat bearings to more than 248°F.
- Put bearings on a wire netting or suspend them in the oil tank to prevent them from touching the tank bottom.

- Heat bearings to a temperature 68 to 86°F higher than the lowest temperature required for mounting, because the inner ring will cool a little during mounting.

After mounting, the bearings will shrink in the axial direction as well as the radial direction while cooling. Therefore, while mounting, press the bearing firmly against the shaft shoulder to avoid excessive clearance between the bearing and the shoulder. Mixing different brands of lubricating oil should be avoided.

## MOUNTING BEARINGS WITH TAPERED BORES

Bearings with tapered bores can be mounted on tapered shafts directly or on cylindrical shafts by using tapered adapters or withdrawal sleeves.

Large spherical bearings are often mounted using hydraulic pressure. Figure 10.55 shows two different hydraulic mounting methods. One method is a sleeve with a hydraulic nut. The other method uses a sleeve with pressurized oil. Holes drilled in the sleeve are used to feed oil under pressure to the bearing seat. As the bearing expands radially, the sleeve is inserted axially with adjusting bolts.

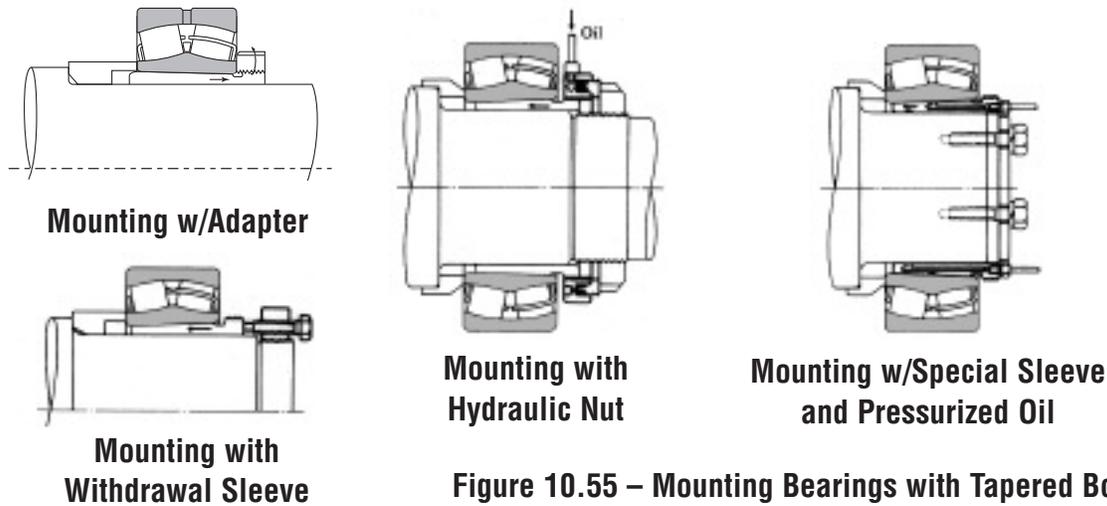

Figure 10.55 – Mounting Bearings with Tapered Bores

The internal clearance of a tapered bore bearing varies with the tightness of the interference fit. It is necessary to check the clearance often as the bearing is being mounted. The bearing should be pressed until the reduction of radial clearance is within the range shown in Table 10.56 on page 348.

For Pe less than 0.13Cr, use the lower half of the reduction range. For heavier loads Pe greater than 0.13Cr, carburized or TL inner rings should be specified and the upper half of the range can be used.

Radial internal clearance can be measured during mounting using a feeler gauge or other appropriate gauges. In this process, the clearances for both rows of rollers must be measured simultaneously and the two values kept roughly the same by adjusting the relative position of the outer and inner rings. This is shown in Fig. 1. The average of the two measurements taken for both rows may be used as the residual internal clearance.

In large bearings, the outer ring may deform slightly into an elliptical shape due to its own weight. In this case, for best results, measurements should be taken at locations **a**, **b**, and **c** (see Fig. 2) and entered into the following equation:

$$\text{radial clearance} = (a + b + c)/2$$

This method is used where the bearing is resting on its outer ring (radial clearance **c** at bottom). When a self-aligning ball bearing is mounted on a shaft adapter, sufficient clearance for easy alignment of the outer ring must be allowed.

**Figure 1**

**Figure 2**

## INSPECTING AND TROUBLESHOOTING

After mounting has been completed, a running test should be conducted to determine that the bearing has been mounted properly.

Small machines may be manually operated to assure that they rotate smoothly. Items to be checked include sticking due to foreign matter, visible flaws, uneven torque, and excessive torque caused by inadequate clearance, mounting error or seal friction.

Large machines which cannot be operated manually, may be started with no load, then the power immediately cut off to allow the machine to coast to a stop. There should be no abnormal vibration, noise or contact between rotating parts. Normal powered operation may be started after this examination. Powered operation should be started slowly, without load, and the operation should be observed until it is determined that no abnormalities exist. Items to be checked during the test operation include abnormal noise, excessive rise of bearing temperature, leakage and discoloration of lubricants. Abnormal noise conditions are indicated by a loud metallic sound or other irregular noise. Possible causes of noise may include incorrect lubrication, poor alignment of the shaft and housing, and foreign matter in the bearing.

Bearing temperature may generally be estimated by the temperature of the outside surface of the housing, but it is more desirable to directly measure the temperature of the outer ring using oil holes for access. Bearing temperature should rise gradually to the steady state level within one to two hours after operation. If the bearing or mountings are improper, bearing temperature may increase rapidly and become abnormally high. Possible causes may include an excessive amount of lubricant, insufficient clearance, incorrect mounting, or excessive friction of the seals. In the case of high speed operation, an incorrect selection of bearing type or lubricating method may also cause an abnormal temperature rise.

Possible causes and countermeasures for operating irregularities are shown in Table 10.57 on page 350.

**Table 10.57 — Causes and Countermeasures for Operating Irregularities**

Irregularities		Possible Causes	Countermeasures
Noise	Loud Metallic Sound	Abnormal Load	Correction of fit, internal clearance, preload, position of housing shoulder, etc.
		Incorrect mounting	Correction of alignment of shaft and housing, accuracy of mounting method.
		Insufficient or improper lubricant	Replenish lubricant or select proper lubricant.
		Squeaking noise	Replacement by low-noise bearings, selection of small clearance bearings.
		Sliding of balls	Adjustment of preload, selection of small clearance bearings, or adoption of softer grease.
	Contact of rotating parts	Correction of labyrinth seal, etc.	
	Loud Regular Sound	Flaws, corrosion, or scratches on the raceways	Replacement of bearing, cleaning, improvement of seals, and usage of clean lubricant.
		Brinelling	Replacement of bearing and careful handling.
		Flaking on the raceways	Replacement of bearing
	Irregular Sound	Excessive clearance	Correction of fit and clearance and correction of preload
Penetration by foreign particles		Replacement of bearing, cleaning, improvement of seals, and relubrication using clean lubricant.	
Flaws or flaking on the ball surfaces		Replacement of bearing	
Excessive amount of lubricant		Reduce amount of lubricant, select stiffer grease.	
Abnormal Temperature Rise	Insufficient or improper lubricant	Replenish lubricant or select proper lubricant.	
	Abnormal load	Correction of fit, internal clearance, preload, position of housing shoulder.	
	Incorrect mounting	Correction of alignment of shaft and housing, accuracy of mounting, or mounting method.	
	Creep of fitted surfaces, excessive seal friction.	Correction of seals, replacement of bearing, correction of fit or mounting.	
Vibration	Brinelling	Replacement of bearings and careful handling.	
	Flaking	Replacement of bearing	
	Incorrect mounting	Correction of squareness between shaft and housing shoulder or side of spacer.	
	Penetration by foreign particles	Replacement of bearing, cleaning, correction of seals.	
Leakage or Discoloration of Lubricant	To much lubrication. Penetration by foreign particles or abrasion chips.	Reduce amount of lubricant, select stiffer grease. Replace bearing or lubricant. Clean housing and adjacent parts.

## HOW TO DISMOUNT BEARINGS

It may be necessary to remove bearings for periodic inspection or for other reasons. If the removed bearing is to be used again, it should be dismantled as carefully as when it was mounted. If the bearing has a tight fit, removal may be difficult. Dismounting procedures and the sequence of removal should be studied carefully before beginning the job.

### Dismounting of Outer Rings

Housings are not normally supplied with facilities to allow easy bearing removal. However, if it is necessary to periodically remove the bearing for inspection or replacement, special features can be incorporated to ease removal. One method is to provide tapped holes, in a minimum of three places equally spaced as illustrated in Figure 10.58. Larger bearings will require more holes. By placing bolts in the holes and tightening evenly, the bearing will be forced out of the housing.

Another method is to provide slots in the housing shoulder as shown here. This allows the use of a press to allow safe removal of the bearing.

### Dismounting of Bearings with Cylindrical Bores

If the mounting design allows space to press out the inner ring, this is an easy and fast method. In this method, the withdrawal force should be imposed only on the inner ring. When it is not possible to use a press, bearing pullers like those shown in Figure 10.58 are often used. The claws of these tools must fully engage the face of the inner ring, therefore it may be necessary to cut grooves in the shoulder to accommodate the tools.

The oil injection method is usually used for the withdrawal of large bearings. Withdrawal is achieved easily by means of oil pressure applied through holes in the shaft. In the case of extra wide bearings, the oil injection method is often used along with bearing pullers.

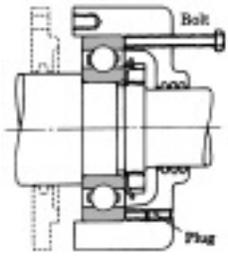

Induction heating is used to remove the inner rings of rollneck type, four row cylindrical roller bearings. The inner rings are expanded by brief local heating and then withdrawn.

### Dismounting of Bearings with Tapered Bores

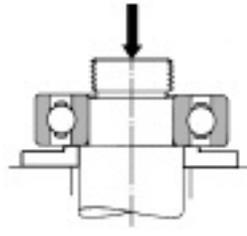

When dismantling relatively small bearings with adapter sleeves, the inner ring is held by a backing ring fastened to the shaft and the nut is loosened several turns. This is followed by hammering on the sleeve using a suitable tool. See Figure 10.58. It may be possible to dismount a withdrawal sleeve by tightening the removal nut. If this procedure is difficult, it may be possible to drill and tap bolt holes in the nut and withdraw the sleeve by tightening the bolts. The two methods for removal of the sleeve are illustrated in Figure 10.58.

Large bearings with tapered bores may be withdrawn easily using oil pressure. Figure 10.58 illustrates the removal of a bearing by forcing oil under pressure through a hole and groove in a tapered shaft to expand the inner ring. When this method is used, the bearing may suddenly move axially when interference is relieved, so a stop nut is recommended for protection. Figure 10.58 also shows a withdrawal using a hydraulic nut.

## CLEANING, INSPECTION AND EVALUATION

### Cleaning Bearings

When bearings are inspected, their appearance should first be recorded and the amount and condition of the residual lubricant checked. After the lubricant has been sampled for examination, the bearing should be cleaned. In general, light oil or kerosene may be used as a washing solution. Dismounted bearings should first be given a preliminary cleaning followed by a finishing rinse. Each cleaning tank should be provided with a metal net to suspend the bearings in the oil without touching either the sides or bottom of the tank.

If the bearings are rotated with foreign matter in them during cleaning, the raceways may be damaged. The lubricant and other deposits should be removed in the oil bath during the initial rough cleaning with a brush or other means. After the bearing is relatively clean, it should be given a finishing rinse. The bearing should be rotated while immersed in the rinsing oil. The rinsing oil must always be kept clean.

### Inspection and Evaluation

After being thoroughly cleaned, bearings should be examined for the condition of their raceways and external surfaces, the amount of cage wear, the increase in internal clearance and degradation of tolerances. These must be carefully checked to determine the possibility of bearing reuse.

In the case of small non-separable ball bearings, hold the bearing horizontally in one hand and rotate the outer ring to confirm that it turns smoothly. Separable bearings such as tapered roller bearings, may be checked by individually examining their rolling elements and the outer ring raceway. Large bearings cannot be rotated manually. However, the rolling elements, raceway surfaces, cages and contact surface of the ribs should be carefully examined visually.

The determination to reuse a bearing should be made only after considering the degree of bearing wear, the function of the machine, the importance of the bearing in the machine, operating condition, and the time until next inspection. If any of the following defects exist, the bearing should be replaced:

- Cracks or dents in the inner or outer ring raceways, rolling elements or cage
- Flaking of the raceways or rolling elements
- Significant scratching of the raceway surfaces, ribs or rolling elements
- Worn cages or loose rivets
- Rust or flaws on the raceway surfaces or rolling elements
- Significant impact or brinell traces on the raceway surfaces or rolling elements
- Discoloration by heat
- Significant damage to the seals or shields of grease sealed bearings

## MAINTENANCE AND INSPECTION

### Correcting Irregularities

In order to maintain the original performance of a bearing for as long as possible, proper maintenance and inspection should be performed. If proper procedures are used, many bearing problems can be avoided. Periodic maintenance following specified procedures is mandatory. This includes supervision of operating conditions, supply or replacement of lubricants, and regular periodic inspection.

Items that should be regularly checked during operation include bearing noise, vibration, temperature and lubrication. If an irregularity is found during operation, the cause should be

determined and the proper corrective action taken immediately. If necessary, the bearing should be dismantled and examined in detail. Refer to Table 10.57 on page 350 for causes and corrections of operating irregularities.

It is very important to detect signs of irregularities early in operation. The **NSK** Bearing Monitor is a device that checks the condition of bearings and gives a warning of any abnormality. It can also be used to stop the machine automatically in order to prevent serious damage. It also helps to improve the level of and attention to maintenance schedules and procedures. Contact **NSK** for further information.

### **Bearing Failures – Cause and Correction**

In general, if rolling bearings are correctly used, they will survive to their predicted fatigue life. Premature failure is usually caused by improper mounting or dismounting, improper lubrication, penetration of foreign material, or inadequate inspection and maintenance.

It is often difficult to determine the real causes of premature failure. If all the conditions leading up to the time of failure are studied, it may be possible to avoid or reduce similar failures in the future.

The most frequent types of bearing failure, along with causes and corrective actions, are shown in Table 10.59 on page 355.

**Table 10.59 — Causes and Countermeasures for Bearing Failures**

	Type of Failure	Probable Cause	Counter Measures
Flaking	Flaking of one-side of the raceway of radial bearings Flaking of the raceways of double row bearings.	Abnormal axial load.	A loose fit should be used when mounting the outer ring of free-end bearings to allow axial expansion of the shaft.
	Flaking of the raceway in a symmetrical pattern	Out of roundness of the housing bore.	Correct the faulty housing.
	Flaking pattern inclined relative to the raceway in radial ball bearings. Flaking near the edge of the raceway and rolling surfaces in roller bearings.	Improper mounting, deflection of shaft, inadequate centering, inadequate tolerances for shaft and housing.	Use care in mounting and centering, select a bearing with a larger clearance, and correct the squareness of the shaft and housing shoulder.
	Flaking of raceway with same spacing as rolling elements.	Large shock load during mounting, rusting while bearing is out of operation for a prolonged period.	Use care in mounting and apply a rust preventive when machine operation is suspended for a long time.
	Premature flaking of raceways and rolling elements.	Insufficient clearance, excessive load, improper lubricant, rust, etc.	Select proper fit, bearing clearance, and lubricant.
	Premature flaking of duplex bearing	Excessive preload.	Adjust the preload.
Scoring and Smearing	Scoring or smearing between raceway and rolling surfaces.	Inadequate initial lubrication, excessively hard grease and high acceleration in starting.	Use a softer grease and avoid rapid acceleration.
	Spiral scoring or smearing of raceway surface of thrust ball bearing.	Raceway rings are not parallel and excessive speed.	Correct the mounting, apply a preload, or select another bearing type.
	Scoring or smearing between the end face of the rollers and guide rib.	Inadequate lubrication, incorrect mounting and large axial load.	Select proper lubricants and modify the mounting.
Cracks	Crack in outer or inner ring.	Excessive shock load, excessive interference fit, incorrect shaft cylindricity, improper amount of sleeve taper, large fillet radius, development of thermal cracks and advancement of flaking.	Examine the loading conditions, modify the fit of bearing sleeve. The fillet radius must be smaller than the bearing chamfer.
	Crack in rolling element. Break in rib.	Advancement of flaking, shock applied to the rib during mounting or dropped during handling.	Be careful in handling and mounting.
	Fracture of cage.	Abnormal loading of cage due to incorrect mounting and improper lubrication.	Reduce the mounting error and review the lubricating method and lubricant.
Indentation	Indentations on raceway in same pattern as rolling elements	Shock load during mounting or excessive load when not rotating.	Use care in handling.
	Indentations on raceway and rolling elements.	Foreign matter such as metallic chips or sand.	Clean the housing, improve the seals, and use a clean lubricant.
Abnormal Wear	False brinelling (phenomenon similar to brinelling).	Vibration of the bearing without rotation during shipment or rocking motion of small amplitude.	Secure the shaft and housing, use oil as a lubricant and reduce vibration by applying a preload.
	Fretting.	Slight wearing of the fitting surface.	Increase interference and apply oil.
	Wearing of raceway, rolling elements, rib and cage.	Penetration by foreign matter, incorrect lubrication, and rust.	Use a different type of seal, clean the housing, and use a clean lubricant.
	Creep.	Insufficient interference or insufficient tightening of sleeve	Modify the fit or tighten the sleeve.
Seizure	Discoloration or welding of raceway, rolling elements, and rib.	Insufficient clearance, incorrect lubrication, or improper mounting.	Review the internal clearance and bearing fit, supply an adequate amount of the proper lubricant and improve the mounting method and related parts.
Electric Burns	Fluting or corrugation.	Melting due to electric arcing.	Install a ground wire to stop flow of electricity or insulate the bearing.
Corrosion and Rust	Rust and corrosion of fitting surfaces and bearing interior.	Condensation of water from the air, fretting, or penetration by corrosive substances.	Use care in storing and avoid high temperatures and high humidity; treatment for rust prevention is necessary when the operation is suspended for a long time.

Directions: The shaft tolerances are determined by adding the top number in the tolerance group to the shaft size and adding the bottom number to the shaft size. This provides the maximum shaft size and the minimum shaft size, respectively.

For example:

Shaft size = 0.4724”

Application = Electric Motor (Recommended shaft fit js6)

Shaft Tolerance (max) = 0.4724” + 0.0002” = 0.4726”

Shaft Tolerance (min) = 0.4724” - 0.0002” = 0.4722”

For example:

Housing bore = 1.2598”

Application = Electric Motor (Recommended Housing fit H7)

Housing Bore Tolerance (max) = 1.2598” + 0.0007” = 1.2605”

Housing Bore Tolerance (min) = 1.2598” + 0” = 1.2598”
